

CFD setup

Highlighted Results for showcase:

Obtained at speed 80 kph = 22.2222 m/s , density of 1.162 kg/m³ , reference/ frontal area = 0.29 m² . Main aspects of car (nosecone + side panels)

Net total drag force = 60.7 N

Net Total drag coefficient= 0.7289

Net total downforce = 28.5 N

Net total downforce coefficient = 0.3429

L/D = 0.47

Downforce generated by nosecone = 9.0196 N , note that nosecone is the only frontal aerodynamic component that generates downforce

% front down force (over the front axle) = (down force of nose cone / total down force) * 100%

= (9.0196 / 28.5) * 100% = 31.65 %

➤ Check Mesh Quality

Mesh Quality:

Minimum Orthogonal Quality = 1.00154e-01 cell 448646 on zone 3754 (ID: 1170250 on partition: 1) at location (1.81738e+00, 4.11892e-01, 2.68951e-01)

Maximum Aspect Ratio = 6.15272e+02 cell 117729 on zone 3754 (ID: 271213 on partition: 0) at location (1.82014e+00, 4.32322e-01, 2.70841e-01)

Turbulent Viscosity

Note: The Reynolds number based on car length is about 4 million, so we will assume the flow to be fully turbulent. Therefore, k-omega SST model is used for this simulation. Also, the curvature correction option is activated to consider the streamline curvature and system rotation.

Help

Note: For the front and rear wheels, the rotation axis origin is set.

The angular speed of the wheels, $\omega = v/r_{\text{wheel}} = 22.2222 / 0.229 = 97.04 \text{ rad/s}$

The rotation of axis is in the z direction according to the right-hand rule

Note: The tunnel walls are set as a zero specified shear to simulate a free slip wall

➤ Solutions

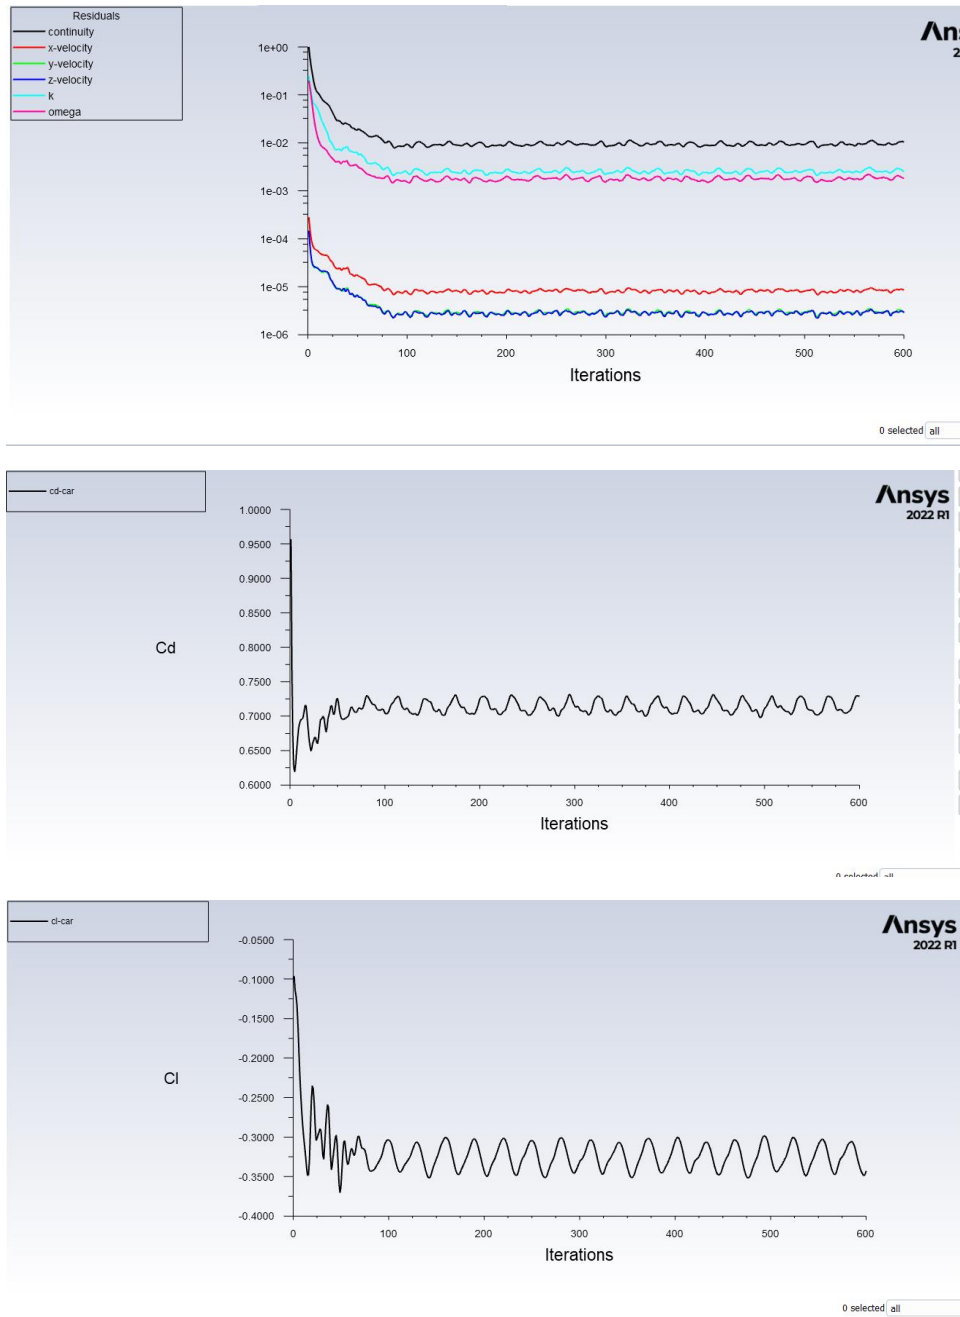

Note: Solutions controls, and convergence conditions are set at the software default value

Note: The simulation is run for 600 iterations, and it's estimated to be completed in 10 hours.

➤ Results:

Note: Global residuals and drag and lift monitors are oscillating which is due to the vortex shedding caused by the interaction of the car and the air. The latter is an expected behavior as this is an inherently unsteady flow problem. The plots of drag and lift coefficient seem to have stabilized past 200 iterations and oscillate around an average value.

➤ **Post-Processing & analysis**

• **Estimated total net drag and lift forces & coefficients**

1) Average total and local drag forces:

Forces - Direction Vector (1 0 0)

Discussion Note:

that the nosecone and wheels, especially the front wheels contribute significantly to the overall drag.

The total lift forces as well as the corresponding lift coefficients have a negative sign , which means that the car is experiencing a net force in the negative y direction (downforce). This force act to keep the car on the ground at this speed.

Net total drag force = 60.7 N

Net Total drag coefficient= 0.7289

Net total downforce = 28.5 N

Net total downforce coefficient = 0.3429

L/D = 0.47

- **Contour Plots**

Contour plots are important to understand the general flow field around the car

1) Velocity plot

This contour plot helps us identify the low and high velocity regions

We can see that the velocity at the front of the car decelerates sharply to zero. This is called a fluid stagnation point. Also, low velocity region is created behind the car which is referred as wake.

2) Static Pressure plot

Nota that there is a high pressure region at the nose and a low pressure region behind the car. The high pressure in front of the car is due to flow stagnation and the low pressure region in the wake is due to the flow separation and subsequent flow reversal behind the car. Note that there is a low pressure region in the nose cone follow floor which is lower than the pressure in the upper part. The latter is what creates the downforce due to venturi effect

- Vector Plots

- 1) Velocity vector plot

Because of the rotational motion of the wheels, we see that the air flow near the wheels has a strong rotational component. Furthermore, flow vortices can be observed which are regions of rotating flow
